- **设计选择（Design choices）**：指在构建模型过程中，从数据处理到模型架构搭建的一系列决策。在数据处理方面，包括对输入数据的处理方式，如是否进行归一化，像文中提到的将输入数据通过公式$x \leftarrow \frac{x-\mu}{\sigma^2}$进行归一化处理，以提升训练效果；在模型架构上，选择使用何种神经网络结构，如全连接神经网络、卷积神经网络或循环神经网络等，不同结构适用于不同类型的数据和任务。
- **超参数调整（Hyperparameter tuning）**：超参数是在模型训练前需要人为设定的参数，无法通过模型训练直接学习得到。例如学习率，它决定了模型在训练过程中参数更新的步长。合适的学习率对模型训练至关重要，学习率过小会使训练速度缓慢，还可能陷入局部最优解；学习率过大则可能导致训练过程不稳定，错过最优解。除学习率外，还有批处理大小、神经网络的层数和神经元数量等都是超参数。调整超参数的方法有试错法、网格搜索、随机搜索等，旨在找到一组最优超参数，使模型性能达到最佳。

Lectutorial 3: Design choices & Hyperparameter tuning

Normalisation, Learning rate, Faster Optimisers & Hyperparameter tuning

Instructor: Thomas Lacombe

归一化、学习率、更快的优化器与超参数调优

Learning outcomes

- Understand the effect of input normalisation on neural network training.
- Understand Batch Normalisation principles and effects on training
- Understand several possible approaches to tuning the learning rate
- Understand different optimisation algorithms based on adaptive learning rate (Momentum, AdaGrad, RMSProp, ADAM)

Activation functions, weights initialisation & regularisation

激活函数、权重初始化、正则化
“ Activation functions, weights initialisation & regularisation ”
意为“ 激活函数、权重初始化与正则化 ”，是神经网络中的重要概念：
- **激活函数（Activation functions）**：
激活函数为神经网络引入非线性因素，使网络能够学习复杂的模式。若没有激活函数，多层神经网络就等价于一个线性模型，其表达能力会非常有限。常见的激活函数有Sigmoid函数、ReLU函数等。Sigmoid函数将输入映射到(0, 1)区间，公式为$\sigma(x)=\frac{1}{1 + e^{-x}}$ ，常用于二分类问题的输出层；ReLU函数表达式为f(x)=max(0, x)，计算简单，能有效缓解梯度消失问题，在隐藏层中应用广泛。

- **权重初始化（weights initialisation）**：
在神经网络训练开始前，需要对权重进行初始化。合适的初始化方式对模型的训练和性能至关重要。若权重都初始化为0，会导致神经元在训练过程中学习到相同的特征，破坏网络的对称性，无法有效学习。常用的初始化方法有随机初始化，如使用正态分布或均匀分布来生成初始权重；还有Xavier初始化、Kaiming初始化等，这些方法能根据网络的结构和激活函数的特性，合理地初始化权重，使信号在网络中更有效地传播，加快收敛速度。

- **正则化（regularisation）**：正则化是防止神经网络过拟合的重要手段。过拟合时，模型在训练集上表现很好，但在测试集或新数据上表现很差。L1和L2正则化是常见的方法，L2正则化也叫权重衰减，通过在损失函数中添加权重向量的L2范数（平方和的平方根）的惩罚项，使权重值趋向于更小，避免权重过大导致模型过于复杂，增强模型的泛化能力。此外，还有Dropout正则化，它在训练过程中随机“ 丢弃 ”一些神经元及其连接，减少神经元之间的共适应性，迫使网络学习更鲁棒的特征。

Normalising inputs

Normalising inputs of a NN:

这三张图展示了数据在不同状态下的分布情况，可能用于说明数据归一化等操作的效果。

从左到右推测：

- 第一张图是原始的二维数据分布，数据点在x_1和x_2构成的平面上分散分布，x_1轴大概范围到 5 ，x_2轴大概到 3 。
- 第二张图可能是对数据进行了中心化操作，数据点围绕原点聚集，说明数据的均值被调整到了原点附近。
- 第三张图可能是在中心化基础上，还进行了一定的尺度变换之类的处理，数据分布更加分散和均衡 ，进一步规范了数据的分布形态。

$$x \leftarrow \frac{x - \mu}{\sigma^2}$$

“Normalising inputs” 即输入归一化，是对神经网络输入数据进行预处理的一种关键操作，公式为$x \leftarrow \frac{x-\mu}{\sigma^2}$ ，在神经网络训练过程中具有重要意义：

- **加快训练速度**：归一化使输入数据处于相似的尺度，避免某些特征因数值过大或过小，导致模型训练时参数更新的步长不一致。例如，在训练图像识别模型时，若图像像素值未归一化，不同图像的像素值范围差异大，模型在学习时难以快速收敛。而经过归一化后，模型能更高效地学习特征，加快训练进程 [1] 。
- **降低梯度消失 / 爆炸风险**：在神经网络中，梯度消失或爆炸会使训练无法正常进行。当输入数据未归一化时，各层输入数据的分布差异大，经过多层网络传递后，梯度可能会变得极小（梯度消失）或极大（梯度爆炸） 。输入归一化可使各层输入数据分布相对稳定，降低这种风险，保证训练的稳定性和有效性 [2] 。

符号含义

- x：表示原始数据中的某个样本或特征值。在实际应用场景中，它可以是图像的像素值、文本数据的特征表示、传感器采集的数据值等。
- μ：代表数据的均值，即所有样本数据的平均值。计算均值是为了衡量数据的中心位置。
- σ^2：表示数据的方差，用于衡量数据的离散程度，即数据的分布范围和波动情况。方差越大，数据越分散；方差越小，数据越集中。

Normalising inputs

- **Why normalising inputs?**

→Makes training faster.

→Reduces risk of vanishing/exploding gradients.

Images source: Andrew Ng

Batch normalisation

- Batch norm = normalising the input of each layer to enable faster training in each layer.

1. Computes the mean of the layer's inputs: μ
2. Computes the variance of the layer's inputs: σ^2
3. Compute the normed input value of each neuron in the layer:

$$z_{norm} = \frac{z - \mu}{\sqrt{\sigma^2 + \varepsilon}}$$

4. Compute: $\tilde{z} = \gamma * z_{norm} + \beta$ (γ and β are learnable parameters)

- Running mean and variance are calculated during training and used at prediction time.

- **符号含义**：
  - z_{norm}：表示经过归一化后的输入值，即每个神经元最终得到的归一化后的输入。
  - z：代表归一化之前，该神经元原本的输入值，它可以是前一层神经元的输出经过加权求和等操作后的结果。
  - μ：是当前 mini - batch 数据中，该神经元所有输入值的均值。通过计算均值可以衡量这批数据的中心位置。
  - σ^2：为当前 mini - batch 数据中，该神经元所有输入值的方差，用于衡量数据的离散程度，方差越大说明数据越分散。
  - ε：是一个很小的正数，比如10^{-8}，引入它是为了防止分母$\sqrt{\sigma^2}$为 0 的情况，保证计算的稳定性。
- **计算过程及作用**：公式通过将原始输入值z减去均值μ，再除以方差σ^2加上一个小正数ε后的平方根，实现对神经元输入值的归一化。归一化后的数据分布更稳定，有助于减少内部协变量偏移，加快神经网络的训练速度，还能使模型在训练时更稳定，不易出现梯度消失或梯度爆炸的问题。

"Compute: $\tilde{z} = \gamma * z_{norm} + \beta$($\gamma$ nd β are learnable parameters)" 意思是进行计算：$\tilde{z}$等于可学习参数γ乘以归一化后的输入值z_{norm}，再加上可学习参数β。

公式解释

- **符号含义**：
  - $\tilde{z}$：是经过批量归一化最终得到的输出值，这个值会作为下一层的输入。
  - γ：是一个可学习的缩放参数（scale parameter），它的作用是对归一化后的数据进行缩放调整，通过训练学习到合适的值，以帮助模型更好地拟合数据。
  - z_{norm}：是之前计算得到的归一化后的输入值，通过公式$z_{norm} = \frac{z-\mu}{\sqrt{\sigma^2+\varepsilon}}$计算得出。
  - β：是一个可学习的偏移参数（shift parameter），用于对缩放后的数据进行偏移操作，同样也是在训练过程中学习到合适的值。
- **计算过程及作用**：在对神经元输入进行归一化得到z_{norm}后，直接使用这个归一化的值可能会限制模型的表达能力。通过引入可学习的参数γ和β，模型可以根据数据的特征，学习到对归一化数据的最佳缩放和偏移方式，使得模型既能享受归一化带来的稳定训练的好处，又能保持足够的表达能力来学习复杂的模式。

Batch normalisation - Regularisation effect

- Batch norm uses the mean and variance of mini-batches, and not the entire dataset.
- It introduces some noise in the neuron values, therefore in the activation values.

→This leads to some regularisation effect.

- Similar effect than using dropout.

- Also reduces the influence of weight initialisation!

How to improve learning? Learning rate

$$w \leftarrow w - \alpha * \nabla_w g(w)$$

- "One hyperparameter to rule them all."
  - Often seen as the most important hyperparameter to tune.
- Hard to know in advance what will be the best value.
  - Trial/error (common range: $10^{-6} < \alpha < 1.0$)
  - Grid/random/etc. search, optimisation techniques.

Choosing a learning rate

- Learning rate value vs curvature of the loss function

- The right learning rate depends on the slope!

- If α too small: learning will be slow and risk of local minima.
- If α too big: risk of overshooting (especially if slope is steep).

Learning rate

- **Learning rate decay schedule**
  - Common practice: decrease learning rate over time (learning rate decay).
  - E.g., linear decay.
  - Linear decay for set number of iterations and then constant.

- **Adaptive learning rates strategies**
  - Monitors the model's performance and adapt the learning rate in response.
  - Reduces learning rate when performance plateaus.
  - Increases learning rate when performance does not improve for a number of iterations.

Learning rate decay schedule

- A common practice: decaying learning rate as learning progresses.

- Why?
  - → Cost function less steep as you come close to an optimum.
  - → Decaying the learning rate allows to take smaller steps when approaching the optimum.

- Finding the right decay schedule is non-trivial.
  - Time-based: Linear decay, exponential decay?
  - Step-based: how much to drop every how many epochs?

https://machinelearningmastery.com/learning-rate-for-deep-learning-neural-networks/

Hyperparameter tuning, batch-norm and learning rate schedule

Algorithms with adaptive learning rate

- SGD uses a fixed learning rate value.
- Other gradient optimisation algorithms implements adaptive learning rates.
- Adagrad, RMSProp, AdaDelta, ADAM, etc.
- Adaptive learning rate strategies generally outperform fixed and not well tuned learning rates.

Oscillations in learning

- **Problem**: oscillations make training slower and increase the risk of overshooting if the learning rate is too high.

Add momentum

- **Momentum mechanism**: includes an exponentially decaying weighted average of previous gradients in the weight update.
  - Usually used with mini-batch Gradient Descent.

$$w \leftarrow w - \alpha \nabla_w g(w)$$

Without momentum

Momentum update

$$v_t = \beta v_{t-1} + (1-\beta)\nabla_w g(w)$$

$$w \leftarrow w - \alpha v_t$$

With momentum

Images source : https://cs231n.github.io/neural-networks-3/, https://www.willamette.edu/~gorr/classes/cs449/momrate.html

AdaGrad

- **Ada**ptive (sub)**Grad**ients algorithm: decays the learning rate based on the sum of previous squared gradients for each individual weight.

$$v_t = v_{t-1} + (\nabla_w g(w))^2$$

$$w \leftarrow w - \frac{\alpha}{\sqrt{v_t + \varepsilon}} \nabla_w g(w)$$

- Adapts the learning rate for each variable/dimension (i.e., weight).
- Reduces the influence of weights with high gradients and increase the influence of weights with lesser gradients (infrequent updates).

Duchi, J., Hazan, E., & Singer, Y. (2011). Adaptive subgradient methods for online learning and stochastic optimization.

AdaGrad

- **Problem with Adagrad**: it is very slow and could stop before reaching the minimum!

- Caused by sum of squared gradients monotonically increasing.

$$v_t = v_{t-1} + (\nabla_w g(w))^2$$

$$w \leftarrow w - \frac{\alpha}{\sqrt{v_t + \varepsilon}} \nabla_w g(w)$$

RMSProp

- **R**oot **M**ean **S**quared **Prop**agation algorithm: extension of Adagrad, introducing a decaying sum of squared gradients.

$$v_t = \beta v_{t-1} + (1-\beta)(\nabla_w g(w))^2$$

$$w \leftarrow w - \frac{\alpha}{\sqrt{v_t + \varepsilon}} \nabla_w g(w)$$

- Keeps the sum of squared gradients under control by applying a decay factor.
- RMSProp does not suffer from problem mentioned for Adagrad.

Lecture 6e rmsprop: Divide the gradient by a running average of its recent magnitude, Geoffrey Hinton

ADAM

- **Adaptive Moment Estimation** algorithm: combines momentum and RMSprop to go even faster!

$$m_t = \beta_1 m_{t-1} + (1-\beta_1)\nabla_w g(w) \qquad v_t = \beta_2 v_{t-1} + (1-\beta_2)(\nabla_w g(w))^2$$

$$\hat{m}_t = \frac{m_t}{1-\beta_1^t} \qquad \hat{v}_t = \frac{v_t}{1-\beta_2^t}$$

$$w \leftarrow w - \frac{\alpha}{\sqrt{\hat{v}_t + \epsilon}}\hat{m}_t$$

- ADAM usually achieves good result fast on a good range of tasks → safe as a first choice.

Kingma, D. P., & Ba, J. (2014). Adam: A method for stochastic optimization.
Coursera video about bias correction

When are ADAM & co. useful?

- **Saddle points / Plateaus**

Local optima?

- Not likely to encounter a local optima with a large NN.
- High number of parameters → high number of dimensions for the cost function.
- A local optima (e.g., minima) require convex/concave shape in every dimension, which is very unlikely.
- More likely to get saddle points.
